Histogram Processing Techniques

```
graph TD; A[Histogram Processing Techniques] --> B[Sliding]; A --> C[Stretching]; A --> D[Equalization];
```

Sliding

Stretching

Equalization

➤ Histogram Sliding

- In Histogram **sliding**, the complete histogram is shifted towards rightwards or leftwards.
- When a histogram is shifted towards the **right or left, clear changes are seen** in the brightness of the image.
- The brightness of the image is defined by the intensity of light which is emitted by a particular light source.

T

➤ Histogram Sliding

- This technique consists of simply **adding or subtracting a constant brightness value** to all pixels in the image. The overall effect is an image with comparable contrast properties, but **higher or lower average brightness**, respectively. `imadd` and `imsubtract` functions can be used for histogram sliding.
- When implementing histogram sliding, **you must make sure that pixel values do not go outside the greyscale boundaries**. An example of histogram sliding is given below:

➤ **Matlab code**

```
A = imread('Penguins_grey.jpg');  
  
imshow(A),title('Original Image');  
  
B=im2double(A);  
  
bright_add = 0.2;  
  
imhist(A), title('Original Histogram');  
  
C=B+bright_add;  
  
imshow(C),title('New Bright Image');  
  
imhist(C), title('New Histogram');
```

➤ Example

FIG 10

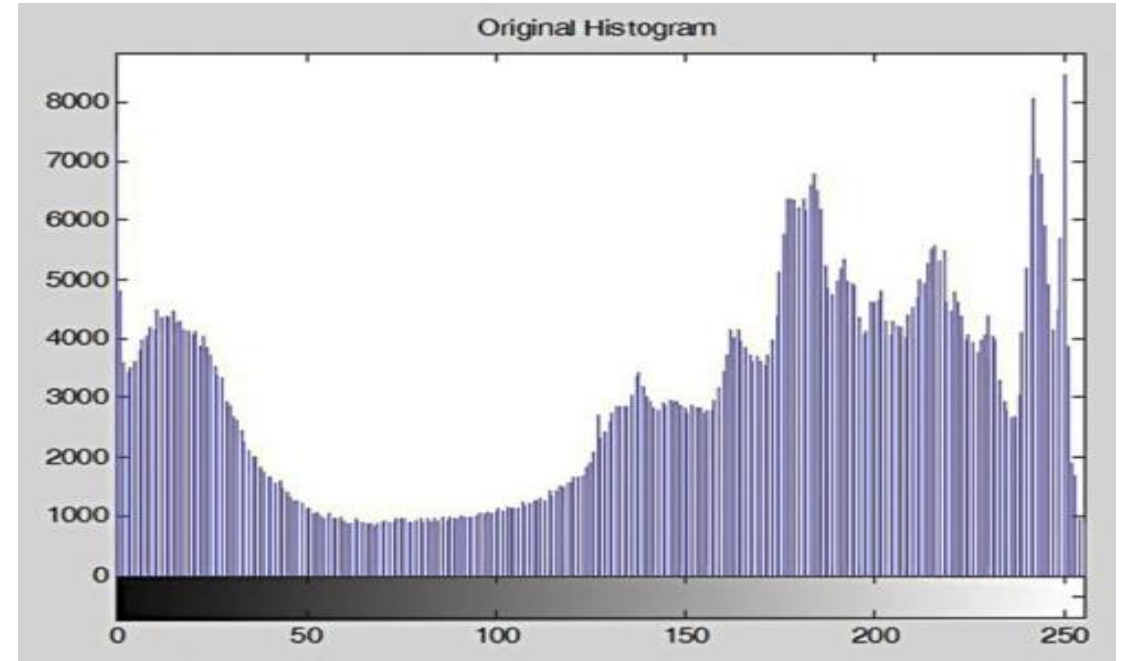

FIG 11

In the example, the image is brightened by adding 0.2 to its pixel values.

Figs 10 and 11 show the original image and its histogram

➤ Example

FIG 12

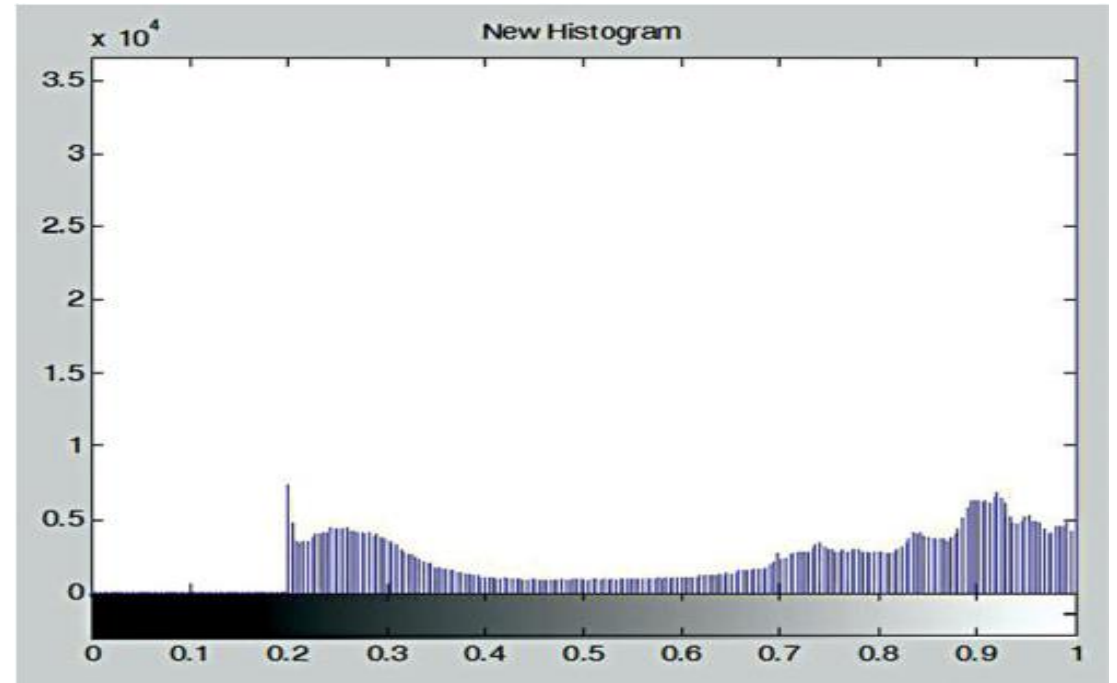

FIG 13

Figs 12 and 13 show the modified image and its histogram, respectively.

➤ Histogram Stretching

- In histogram **stretching**, contrast of an image is increased. **The contrast of an image is defined between the maximum and minimum value of pixel intensity.**
- If we want to increase the contrast of an image, histogram of that image will be **fully stretched and covered the dynamic range of the histogram.**
- From histogram of an image, we can check that the image has low or high contrast.

➤ Histogram Stretching

➤ Histogram Equalization

- Histogram equalization is used for **equalizing all the pixel values** of an image. Transformation is done in such a way that **uniform flattened** histogram is produced.
- Histogram equalization **increases the dynamic range of pixel values** and makes an equal count of pixels at each level which **produces a flat histogram with high contrast image**.
- While stretching histogram, the shape of histogram remains the same whereas in Histogram equalization, the shape of histogram changes and it generates only one image.

➤ Histogram Equalization

(a) Images

(b) Results of histogram equalization. (c) Corresponding histograms.

➤ Example: Fixed Intensity Transformation

- A 4x4, 4bits/pixel image through

1	8	6	6
6	3	11	8
8	8	9	10
9	10	10	7

passes

an intensity transformation

$$s = T(r) = \text{round} \left(\frac{1}{15} r^2 \right)$$

$$1 \rightarrow \text{round}(0.0667) = 0;$$

$$3 \rightarrow \text{round}(0.6) = 1;$$

$$6 \rightarrow \text{round}(2.4) = 2;$$

$$7 \rightarrow \text{round}(3.2667) = 3;$$

$$8 \rightarrow \text{round}(4.2667) = 4;$$

$$9 \rightarrow \text{round}(5.4) = 5;$$

$$10 \rightarrow \text{round}(6.6667) = 7;$$

$$11 \rightarrow \text{round}(8.0667) = 8;$$

The resulting image is:

0	4	2	2
2	1	8	4
4	4	5	7
5	7	7	3

➤ Example: Histogram Change

1	8	6	6
6	3	11	8
8	8	9	10
9	10	10	7

0	4	2	2
2	1	8	4
4	4	5	7
5	7	7	3

Contrast Stretch

➤ General Idea: Make Best Use of the Dynamic Range

➤ Contrast Stretch

General form:

$$s = \begin{cases} \frac{s_1}{r_1} \cdot r & 0 \leq r < r_1 \\ \frac{s_2 - s_1}{r_2 - r_1} \cdot r + \frac{s_1 r_2 - s_2 r_1}{r_2 - r_1} & r_1 \leq r \leq r_2 \\ \frac{2^B - 1 - s_2}{2^B - 1 - r_2} \cdot r + (2^B - 1) \cdot \frac{s_2 - r_2}{2^B - 1 - r_2} & r_2 < r \leq 2^B - 1 \end{cases}$$

Special case → Full-scale contrast stretch:

$$\begin{array}{ll} r_1 = r_{\min} & s_1 = 0 \\ r_2 = r_{\max} & s_2 = 2^B - 1 \end{array} \quad \longrightarrow \quad s = (2^B - 1) \cdot \frac{r - r_{\min}}{r_{\max} - r_{\min}}$$

Typically used: $s = \text{round} \left((2^B - 1) \cdot \frac{r - r_{\min}}{r_{\max} - r_{\min}} \right)$

➤ Example: Full-Scale Contrast Stretch

- Full-scale contrast stretch of a 4x4, 4bits/pixel image

4	8	6	6
6	4	11	8
8	8	9	10
8	11	10	7

- Find when $r_{\min}=4$ $r_{\max}=11$ $2^B - 1 = 15$

$$s = \text{round} \left((2^B - 1) \cdot \frac{r - r_{\min}}{r_{\max} - r_{\min}} \right) = \text{round} \left(15 \cdot \frac{r - 4}{11 - 4} \right) = \text{round} \left(\frac{15}{7} (r - 4) \right)$$

- 4 → round(0) = 0;
- 6 → round(4.29) = 4;
- 7 → round(6.43) = 6;
- 8 → round(8.57) = 9;
- 9 → round(10.71) = 11;
- 10 → round(12.86) = 13;
- 11 → round(15) = 15;

The resulting image is:

0	9	4	4
4	0	15	9
9	9	11	13
9	15	13	6

➤ Example: Histogram Change

4	8	6	6
6	4	11	8
8	8	9	10
8	11	10	7

0	9	4	4
4	0	15	9
9	9	11	13
9	15	13	6

Histogram Equalization

➤ Example

- A 4x4, 4bits/pixel image

2	8	9	9
2	3	10	9
8	3	3	11
8	3	10	11

- First try full-scale contrast stretch $r_{\min}=2$ $r_{\max}=11$

$$s = \text{round} \left((2^B - 1) \cdot \frac{r - r_{\min}}{r_{\max} - r_{\min}} \right) = \text{round} \left(15 \cdot \frac{r - 2}{11 - 2} \right) = \text{round} \left(\frac{15}{9} (r - 2) \right)$$

$$2 \rightarrow \text{round}(0) = 0;$$

$$3 \rightarrow \text{round}(1.67) = 2;$$

$$8 \rightarrow \text{round}(10.00) = 10;$$

$$9 \rightarrow \text{round}(11.67) = 12;$$

$$10 \rightarrow \text{round}(13.33) = 13;$$

$$11 \rightarrow \text{round}(15) = 15;$$

The resulting image is:

0	10	12	12
0	2	13	12
10	2	2	15
10	2	13	15

➤ Example: Histogram Change

➤ Cumulative Histogram

➤ Enhancement Using Arithmetic/Logic Operations

- **Arithmetic/logic** operations involving images are performed on a **pixel-by-pixel** basis between **two or more** images (this **excludes** the logic operation **NOT**, which is performed on a **single** image).

➤ Basics of Spatial Filtering

- As mentioned, some neighborhood operations work with the values of the image pixels in the **neighborhood** and the **corresponding values of a sub-image** that has the same dimensions as the neighborhood.
- The sub-image is called a **filter, mask, kernel, template, or window**, with the first **three** terms being the most prevalent terminology.
- The values in a filter sub-image are referred to as **coefficients**, rather than **pixels**.

➤ Mechanics of spatial filtering

- The process consists **simply of moving** the filter **mask** from **point to point** in an **image**. At each point (x, y) , the response of the filter at that point is **calculated** using a **predefined relationship**.
- For **linear spatial** filtering, the response is given by a **sum of products** of the filter **coefficients** and the corresponding **image pixels** in the area spanned by the filter mask.

➤ **Smoothing Spatial Filters**

- Smoothing filters are used for **blurring** and for **noise reduction**.
- **Blurring** is used in **preprocessing** steps, such as **removal of small details** from an image prior to (large) object extraction and bridging of small gaps in lines or curves.
- **Noise reduction** can be **accomplished** by blurring with a **linear** filter and by **nonlinear** filtering.

➤ 1. Smoothing Linear Filters

- The output (response) of a smoothing, linear spatial filter is **simply** the **average** of the pixels contained in the neighborhood of the filter mask.
- These filters sometimes are called **averaging filters**.

$$\frac{1}{9} \times$$

1	1	1
1	1	1
1	1	1

$$\frac{1}{16} \times$$

1	2	1
2	4	2
1	2	1

$$R = \frac{1}{\Sigma} \sum_{i=1}^n z_i$$

➤ 1. Smoothing Linear Filters Example

(a) Original image, of size 500*500 pixels.

(b) → (f) Results of smoothing with square averaging filter masks of sizes $n=3, 5, 9, 15,$ and $35,$ respectively.

a	b
c	d
e	f

➤ 2. Order-Statistics Filters

- Order-statistics filters are **nonlinear** spatial filters whose response is based on ordering (ranking) the pixels contained in the image area encompassed by the filter, and then replacing the value of the center pixel with the value determined by the ranking result.
- The best-known example in this category is the **median filter**, which, as its name implies, replaces the value of a pixel by the median of the gray levels in the neighborhood of that pixel.
- **Median filters** are quite **popular** because, for certain types of **random noise**, they provide excellent **noise-reduction** capabilities, with considerably **less blurring than linear smoothing** filters of similar size.

➤ 2. Order-Statistics Filters - Median filter

- In order to **perform** median filtering at a **point** in an image, **we first sort** the values of the pixel in question and its neighbors, determine their **median**, and assign this value to that pixel.
- **For example**, suppose that a 3×3 neighborhood has values (10, 20, 20, 20, 15, 20, 20, 25, 100). These values are sorted as (10, 15, 20, 20, **20**, 20, 20, 25, 100), which results in a median of 20.

➤ Example:-

- (a) X-ray image of circuit board corrupted by salt-and-pepper noise. (b) Noise reduction with a 3×3 averaging mask. (c) Noise reduction with a 3×3 median filter.

➤ Sharpening Spatial Filters

- The **principal objective** of sharpening is **to highlight fine detail** in an image or to enhance detail that has been blurred, either in error or as a natural effect of a particular method of image acquisition.
- Uses of image sharpening vary and include applications ranging from **electronic printing** and **medical imaging** to **industrial inspection** and **autonomous guidance** in military systems.

➤ 1. Use of Second Derivatives for Enhancement–The Laplacian

$$\nabla^2 f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2}.$$

$$\frac{\partial^2 f}{\partial x^2} = f(x + 1, y) + f(x - 1, y) - 2f(x, y)$$

$$\frac{\partial^2 f}{\partial y^2} = f(x, y + 1) + f(x, y - 1) - 2f(x, y)$$

$$\nabla^2 f = [f(x + 1, y) + f(x - 1, y) + f(x, y + 1) + f(x, y - 1)] - 4f(x, y).$$

0	1	0	1	1	1
1	-4	1	1	-8	1
0	1	0	1	1	1
0	-1	0	-1	-1	-1
